

Project #3

Michael Schoen, Abdirahman Osman, Illya Starikov

Due Date: Tuesday, December 6th, 2016

For the second project, we were delighted to be able to use a higher level programming language; we¹ decided to apply this new-found excitement to implement a retro game from the 70s: Space Invaders.

Figure 1 – The original space invaders.

1 Project Description

Below we will go into more detail about each individual parts of our project.

¹Illya.

1.1 The Game

The game we initially decided to go with was space invaders. We had intention of doing the game logic on the microcontroller through serial communication; however, we learned early that this was likely not be possible². We describe in *Problems Encountered* how we absolved this. From here, we decided our game would exclusively be in the terminal.

Our game essentially creates a two dimensional array (in three segments — the header to show score and level, the aliens, and the shooter). Then we loop through depending on the input:

- Move the shooter left.
- Move the shooter left.
- Quits the game
- Shoots with the gunner.
- No input meant refresh game.

We achieved the drawing through curses³. Ultimately, we did not get our game fully done, but a good majority of it.

1.2 Music

The formula for each note is

$$\frac{1/4 \text{ Oscillator Frequency}}{\text{Note Frequency}}$$

So for supposing we want to produce the note *C*4,

$$\frac{1/4 \text{ Oscillator Frequency}}{\text{Note Frequency}} = \frac{1/4 \cdot 7.373 \text{ Hz}}{261.63 \text{ Hz}} = 7.045 \text{ ms} \quad (1)$$

To produce the music, we had a function that took in which note and the type of note (16th, 8th, 4th, half or whole note). The function multiplied the

²Our hex file with very basic functionality was 25 kB.

Figure 2 – Text Invaders, our version of space invaders..

base length of a note by a constant depending on the type of note. A 16th note would be multiplied by 1, an 8th by 2, a quarter note by 4, a half-note by 8, and a whole note by 16. We used timers and interrupts for the period of the note and the length of the note.

We used sheet music to get the notes. For speeding and slowing down the music, the type of note was just multiplied by 2 or divided by 2 respectively.

1.3 Interactive User Interface

The menu goes through three stages; printing the pen-rose triangle background, printing options, then allowing the selection of items. The following are printed

- Counter
- Hurricane’s Eye
- Keyboard

respectively. From there the user has the option to cycle upwards using P_2 (see Figure. 3), cycle down using P_8 , or select using P_5 . The cycle starts with

1 highlighting Counter if P_2 is pressed then Hurricane's eye will be highlighted, and if printed once again Counter will be selected. If the menu user presses P_1 once at the 3rd option (Keyboard) then the menu will cycle back to option 1 and vis versa if P_8 were clicked at the 1st option. Selecting an menu option with P_5 while highlighted will start its respective function. Also each menu option has a corresponding number displayed on a seven segment display.

Figure 3 – The Main Menu.

1.4 Seven Segment Display

For the seven segment display, we had to set P_2 to be push/pull so that the display would receive enough power. We then looked up the correct values to output to the pins to make each number show up on the display and used those values in the increment/decremented function as well as the simple function that lets you display any number. We used the data sheet for the seven segment display to see how to connect it on the breadboard.

1.5 Keyboard

Our keyboard has a C scale set to switches $P_1 \cdots P_8$ with P_9 escaping to the menu. Each switch uses the corresponding light associated with its position save P_9 which is the escape button.

1.6 Curses

In order to print to any part of the screen we needed to implement a structure to send ANSI control sequences and characters to the terminal using `uart_get()` as a base. To do this we implemented an 8051 port of curses that takes in (x, y) coordinates as arguments for printing `chars` and `strings` at any defined (x, y) location. This allows for the implementation of the menu since it requires printing of options in sometimes nonlinear fashion.

We spent a great deal of time with the serial communication aspect of the board. With this we found a whole host of issues associated with printing characters to a terminal, printing to an arbitrary location, control sequences, fluctuation in crystal timings, and requesting information from a terminal.

2 Problems Encountered

Below we will list some of the “several” problems we ran into.

2.1 Memory Constraints

By far, the biggest problem we encountered was the memory constraint. The 8051 has 8 kB of memory; our code base, with the exclusion of all the `malloc`s⁴, it is roughly 25 kB — a size a bit larger than the 8051 allows. Our workaround was to fight fire with fire.

Instead of “dumbing” down our game⁵ to get it to fit, we decided to have an external interface; specifically, a port sniffer. It would listen for input from the 8051, and if there is a signal on the serial port, use that as input. If not, default to the keyboard input.

Ultimately, we were unsuccessful with the port sniffer. Originally, we had tried to use a Linux port sniffer so we can just embed it into our program, `slsnif`⁶. Unfortunately this port sniffer does not support “legacy” ports, and the 8051 falls in this category. So we moved onto a Windows port sniffer,

⁴Since `unsigned char` = 1 B, the terminal window will roughly be 20 height × 80 width, we can roughly expect 1.6 kB to be allocated on the heap; a non-insignificant amount compared to 8 kB.

⁵According to back of the hand calculations, a space-optimized version of the game would still be 7 kB. This was likely to be impossible.

⁶Can be found at <https://sourceforge.net/projects/slsnif/>.

`Serial Input For Windows`⁷. This too did not work, because we could only have one interface use the serial port, so we would need a dedicated socket to intercept the `COM1` port's input — something we were not familiar with.

Ultimately, we were simply unsuccessful and had to scrap this.

2.2 Printing Lines and Columns.

We had an issue with the timing crystals of the Simon board where the board heating up would cause the serial port to start printing unrecognizable characters. This lead us to think we were causing a segfault when we was printing string literals. This caused hours of wasted time since nothing we could change would cause the board to start printing what we wanted, but one afternoon after hours of exhaustive research and help at the lead sessions the conclusion was reached that heat changes were causing the board to lose its timing and print out nonsense. The fix for this was to let the board cool off while writing code. After this change garbage outputs dropped significantly.

2.3 Seven Segment Display Buttons

One problem we ran into was some of the buttons use the same pins as we used for the seven segment display. The display used push/pull which makes the buttons not work, so we had to carefully chose buttons that didn't use the same pins.

3 Individual Features

- Michael Schoen — 33% Contribution
 - Song
 - Seven Segment Display
- Abdirahman Osman — 33% Contribution
 - Port Serialization
